MUNICIPAL WASTEWATER TREATMENT SYSTEMS

As of March, 1984, there were 381 municipal wastewater treatment facilities in Ontario having a combined total capacity of 5.768 thousands of cubic metres per day ($1000m^3$) or 1,269 million Imperial gallons per day (mIgd). The total population served by these facilities is 7.1 million.

MUNICIPAL WATER SUPPLY SYSTEMS

As of March, 1984, there were 472 municipal water supply systems in Ontario having a combined total capacity of 9,423 thousands of cubic metres per day ($1000m^3$) or 2,072 million Imperial gallons per day (mIgd). Surface water supplies number 195 and account for approximately 86% of the total capacity while ground water supplies number 277 and account for the remaining 14%. The total population served by both ground and surface water sources is 7.5 million.

INTRODUCTION

The Ministry of the Environment is concerned with the protection and enchancement of the natural environment. For example, the release of untreated or partially treated sanitary wastes to a lake or river may render the watercourse, particularly in the immediate discharge area, unusable for practically all purposes. This condition creates a threat to public health and is disruptive to plant and animal life cycles; therefore, the adequate treatment of wastes to produce a satisfactory effluent for discharge to a watercourse is a major concern of this Ministry.

When a body of water is needed for the assimilation and dilution of treated wastes then consideration must be given to all of the other uses of water, such as public, agricultural and industrial water supply, recreation, aesthetic enjoyment and the propagation of fish and wildlife. It is evident that Ontario's water resources must meet many needs and in order to assist with the administration of these needs, the Ministry of the Environment has produced a publication entitled "Water Management" which outlines "goals, policies, objectives and implementation procedures of the Ministry of the Environment", necessary to ensure the sound management of water and wastewater across the province. Copies may be obtained from the Water Resources Branch, 1 St. Clair Avenue West, (Telephone: 965-6954). In addition, criteria for drinking water is outlined in a publication entitled, "Ontario Drinking Water Objectives", which is available from this Ministry's Information Services Branch at 135 St. Clair Avenue West, (Telephone: 965-7117). Both of the above mentioned publications may be obtained from the Publications Centre, Ministry of Government Services, 880 Bay Street, 5th Floor, Toronto.

With regard to the meeting of these goals and objectives, the Ministry inspects and regulates all communal water and wastewater facilities, and monitors the performance of the treatment plants and their effluent qualities with routine and special sampling programs. The administration of these services and programs is carried out on a regional basis. To complement the sampling programs and the various water quality management programs, the Water and Wastewater Management Section of the Water Resources Branch, in co-operation with our Regional offices, has produced this publication from its EDP system to provide a comprehensive listing of all major municipal wastewater and water treatment facilities operating in Ontario.

This publication has two major parts. PART I lists the wastewater treatment facilities and PART II lists the water treatment facilities. Each part begins with a brief description of the various treatment methods, followed by a provincial summary of the existing treatment types and their hydraulic capacities. A complete listing of the works is then provided.

Since the delivery of programs and services by this Ministry is carried out on a regional basis, it is therefore, logical to group these treatment works under the Ministry's six regions. Accordingly, each one of our regions is first defined by means of a map page and then all treatment works for that particular region are listed alphabetically by municipality. An additional list of the plants which are located in each of the larger or regional municipalities has been prepared on blue paper.

Very large systems, which serve more than one municipality, are shown at the end of each region's data on pink paper and the definition of these, 'area systems' is described below.

Area-Systems - "Area Wastewater Treatment Systems" and "Area Water Supply Systems"

When a municipality experiences sustained growth, eventually the serviced area of its treatment facility extends beyond its municipal boundaries. Once this condition occurs to the point where it becomes necessary to size the treatment works and major service mains to accomodate a much larger area, the system is, for the purposes of this publication, defined as an "Area Wastewater Treatment System", or an "Area Water Supply System".

MUNICIPAL WASTEWATER

PART I

PART 1 - WASTEWATER TREATMENT

There are many types of wastewater treatment processes for sanitary wastes but the major treatment methods are variations of the principles which nature uses to purify a river or other body of water. Basically, the essential processes such as sedimentation and the biological breakdown of wastes are speeded up in the treatment plant, with the end result being a quality effluent which places a minimum amount of strain on the environment. A chemical precipitation process, specifically to control the phosphorus content of the effluent, has been applied to the majority of wastewater facilities in Ontario. This is seen to be a key factor in controlling nuisance algae in watercourses.

At present, three basic treatment methods are employed in Ontario and these may be categorized as "primary", "secondary" and "lagoon" treatment. In the primary stage, solids are allowed to settle and are removed as sludge from the wastewater. The secondary stage uses biological processes to purify the wastewater even further. Lagoons or waste stabilization ponds use both the physical (settling of solids) and biological treatment processes to remove impurities from the wastewater. Tertiary processes which further remove impurities are now being installed at specified locations to meet more stringent receiving water quality requirements.

It is important to note that over 90% of the municipal wastewaters in Ontario receive secondary treatment or better.

The efficiency of all treatment whether primary, secondary, lagoons or tertiary are generally rated in terms of the percentage removal of Biochemical Oxygen Demand (BOD) and the percentage removal of Suspended Solids (SS). BOD is simply the amount of oxygen uptake by bacteria to decompose the wastes and 'SS' are the organic and inorganic substances suspended in the wastewater.

1. PRIMARY TREATMENT

Wastes entering a plant for treatment are passed through a screen to remove items such as rags, sticks, etc. which may clog pumps or pipes. After screening, the wastes are directed into a grit chamber where sand and small stones are allowed to settle. With the grit removed, the mechanics of settling are further employed to remove the inorganic suspended solids in a primary sedimentation tank or clarifier. The material (sludge) which is removed by the primary clarifier is transferred to a digester or other treatment facility where it is suitably stabilized prior to final disposal. Primary treatment generally removes 40 to 60 percent of the suspended solids and in so doing it achieves 30 to 40 percent reduction of BOD. To complete primary treatment, the effluent from the clarifier is usually chlorinated before being discharged to a receiving stream, river or lake. Chlorination reduces the number of disease causing bacteria. The effluent produced from primary treatment is of a lower standard of quality than is achieved by secondary treatment; consequently, this form of treatment is used only when it will meet the water quality requirements of the receiving body of water.

2. SECONDARY TREATMENT

Secondary treatment, commonly referred to as biological treatment removes up to 95% of the BOD through the action of bacteria. The term biological refers to the micro-organisms present in the wastewater. These micro-organisms are utilized to break down the organic matter, are settled out in the secondary clarifier, and removed as sludge to the digester or other treatment prior to final disposal. The treated wastewater is now a clear liquid effluent, which is usually chlorinated before discharge to the receiving stream, river or lake.

There are various forms of secondary treatment but the 'activated sludge process' is by far the most popular method used today.

2.1 ACTIVATED SLUDGE PROCESS

The activated sludge process reduces the organic content of the wastes in as short a time as possible by effectively maintaining biological action on the incoming wastes. This is done by introducing a highly developed bacterial community, 'activated sludge', to the new wastes as soon as possible, usually at the beginning of the aeration sections. The efficiency of this process is ensured by providing a suitable environment for the micro-organisms, which means, supplying optimum amounts of food in the form of wastes, oxygen through aeration and a temperature high enough to maintain the desired growth of the microbes.

The following treatment types, are modifications of the activated sludge process.

a) Conventional Activated Sludge Process

In this process, the effluent from the primary treatment stage is conveyed to an aeration section where it is thoroughly mixed by the introduction of air for approximately 6 to 8 hours. The air provides sufficient oxygen and contact through agitation with the new wastes to ensure that an efficient decomposition of wastes occurs. An optimum balance between the incoming food (primary effluent) and the population of the mixed biological community is maintained by adding a portion of the activated sludge to the beginning of the aeration section. Excess activated sludge together with some liquids are directed to the digesters where they receive further treatment. A clear high quality effluent is produced and the removal of BOD and suspended solids ranges from 90 to 95 percent.

b) High Rate

The high rate system was developed by overloading the conventionally designed activated sludge plants. The organic load to the aeration sections is the highest of any of the activated sludge processes. The aeration time is also shorter (1 to 3 hours). Excess activated sludge is directed to a digester for stabilization before final disposal. The high rate process allows for a higher volume of waste to be handled in a shorter period of time, which makes for a more economical operation. A primary treatment section may or may not be present, and this method is generally used where industrial wastes are encountered.

The high rate type of treatment is reported to have a removal rate of BOD and suspended solids in the 80 to 85 percent range.

c) Extended Aeration

The incoming wastes are immediately placed in an aeration section without primary settling and a longer aeration time is employed usually 18 to 24 hours. Due to the long aeration period a more complete decomposition or oxidation of the wastes occurs.

As with the conventional secondary, a high level of biological activity is maintained throughout the aeration tank by returning some of the activated sludge to the raw sewage influent. Excess activated sludge are placed in a holding tank or a digester prior to final disposal. The reduction in BOD is usually in excess of 90%.

d) Contact Stabilization

This process provides a means of varying the contact time between the incoming wastes and the activated sludge. The raw sewage is directed to a small chamber called a contact tank in which aeration is provided for 1 to 2 hours. After this short aeration period the wastes undergo settling and the resulting sludge is re-aerated for a further 2 to 6 hours. The total aeration time of the sludge ranges from 3 to 8 hours which allows for the production of the activated sludge required in the contact aeration tank. Excess activated sludge are placed in a holding tank or a digester prior to final disposal.

The removal of suspended solids and BOD is similar to the conventional secondary method.

e) Oxidation Ditch

An oxidation ditch is a retention channel constructed in the shape of an oval race track and equipped with a aerating device which circulates the wastewater around the channel and provides oxygen for the micro-organisms utilized by this activated sludge process. Treated wastewater is drawn off into a settling tank as new wastes are added. Activated sludge from the settling basin is recirculated into the oxidation ditch while the waste sludge is removed for final disposal. The effluent from the settling tank is clear and of good quality with BOD and suspended solids removal ranging from 85 to 90 percent. This process is similar to extended aeration and is usually used in smaller communities.

2.2 TRICKLING FILTER

The trickling filter is a bed of stones from 3 to 6 feet deep to which primary treated sewage is distributed uniformly across the surface. Bacteria which adhere to and multiply on the surfaces of these stones consume most of the organic matter. Treated water trickles out through a network of pipes in the bottom of the filter where it is collected and directed to a final clarifier before discharge to the receiving stream. BOD and suspended solids removal by this process has been reported from 75 to 90 percent. Trickling filters have generally been employed in the more temperate climates.

2.3 LAGOON, AERATED CELL, AERATED LAGOON

A lagoon is a flat bottomed structure composed of earth dikes and sized to retain the wastewater for a designated period of time. The lagoon utilizes many complex systems which work together in a cyclical manner. For example, the bacteria converts the organic matter into available plant food and promotes the growth of algae. The algae, with the aid of sunlight, produces oxygen which is required to maintain good bacterial activity on the incoming wastes. The bacteria also give off carbon dioxide which is needed to sustain the algae's life cycle. During the retention period these natural processes work together to decompose and effectively stabilize the wastes. The efficiency of these processes are dependent on several factors such as liquid depth, temperature, algae growth, waste characteristics, etc. When conditions are at an optimum, a good quality effluent can be expected.

Some lagoons, or waste stabilization ponds may be aerated, by either mechanical stirring or bubbling air into one small cell (aerated cell) or throughout the entire lagoon (aerated lagoon). Aeration reduces the retention period, increases the capacity of the existing lagoon and is useful in treating some industrial wastes. Eighty to eighty-five percent removal of BOD and suspended solids may be expected.

3. TERTIARY TREATMENT

Tertiary treatment processes are applied to secondary effluent to further upgrade the effluent quality for specific receiving water needs.

In Ontario, the main tertiary processes used on a municipal scale are polishing lagoons and effluent filtration. These are designated as "effluent polishing" in this publication.

a) Polishing Lagoons

Polishing lagoons offer an opportunity for increased BOD and suspended solids removal at a minimum of cost but require a relatively large land area. Secondary effluent is passed into a lagoon where it is retained for several days while the algae-bacterial symbiotic relationship is encouraged to optimize oxidation of the organic waste. A fairly consistent removal of BOD is maintained throughout the year. There is a marked increase in effluent SS during the summer months when algae activity is at its peak and this constitutes a major disadvantage of the polishing lagoon. BOD removals in the order of 40% to 60% from a secondary effluent may be achieved.

b) Effluent Filtration

Filtration of secondary effluent is the most widely applied tertiary process in Ontario. A well designed and operated tertiary filter can achieve a good reduction of suspended solids and is effective in reducing BOD and total phosphorus.

4. PHOSPHORUS REMOVAL

Treatment of phosphorus basically consists of the addition of a chemical which, through precipitation, reduces the phosphorus concentration in the effluent. Phosphorus must be reduced to one part per million (1 ppm) or milligram per litre (mg/l) in all designated plants in the Lower Great Lakes drainage basin. Designated plants in the Upper Great Lakes and Ottawa River drainage basins must reduce influent phosphorus by 80 percent or to 1 mg/l. Phosphorus removal facilities can be incorporated into any existing treatment works and the chemicals generally used are lime, aluminum salts or iron salts. New chemicals to be used in any plant must first undergo treatability studies to determine if the desired reduction of phosphorus is achieved with no upset in plant operation and to ensure that the quality of effluent has not suffered any deterioration.

Important side benefits of increased removal of organic material and suspended solids occur when phosphorus treatment is employed in primary plants and lagoons with seasonal discharge. Secondary plants and continuous discharge lagoons do not enjoy these benefits; however, secondary plants report better settling in the final clarifier.

MUNICIPAL WATER

PART II

PART II - MUNICIPAL WATER TREATMENT

Water is one of Ontario's most abundant natural resources. When used for human consumption, however, it must be chemically and bacteriologically safe. Aesthetic considerations such as temperature, taste, odour, colour and turbidity, are also important in achieving acceptable drinking water. The raw water quality and the intended use of the water supply dictate the degree and type of treatment necessary.

Municipal water supplies are obtained from two main sources: Groundwater, which includes both deep and shallow wells; and Surfacewater, which includes rivers, lakes and reservoirs.

Groundwater is characteristically cool and sustains only slight temperature variations. Generally it requires little treatment to meet the quality requirements for a drinking water supply and is often the first to be investigated as a source. Treatment is only required when analyses indicate that disease organisms may be present or when a potential danger of contamination exists. Disinfection by chlorination is then usually used. Quality in terms of hardness and/or excessive iron are other groundwater quality concerns. Various treatment methods such as ion exchange and/or sequestering are used to combat these problems.

Because groundwater cannot be extracted in sufficient quantities to meet the needs of the rapidly expanding communities, the majority of municipalities in Ontario rely on surface water sources. These waters, affected by pollution and eutrophication, must be treated to provide a safe potable supply acceptable for municipal drinking water requirements. For example, all surface waters contain bacteria; therefore, disinfection by chlorination is necessary to remove pathogenic (disease-producing) bacteria from municipal drinking water supplies. Colour, turbidity, taste and odour, all physical characteristics of raw water, are caused by finely suspended particles and dissolved organic matter that are usually present to some degree in all surface waters. These and other concerns are dealt with by various processes and equipment, some or all of which may be used in a plant depending on the quality of the source of supply. The following information outlines some of the basic water treatment processes.

Screening (Physical Treatment)

The raw (untreated) water is passed through coarse and fine screens and/or microstrainers to remove larger particles and algae.

Disinfection by Chlorination (Chemical Treatment)

Chlorination is usually applied at the beginning (Pre-chlorination) and at the end (Post-chlorination) of the treatment process. Pre-chlorination provides disinfection of the raw water; furthermore, along with active carbon, it can be used to remove taste and odour producing compounds. Post-chlorination establishes a chlorine residual in the treated water ensuring that any remaining disease-producing organisms are killed before delivery to the consumer or storage facility.

Colour, Turbidity and Bacteria Removal by Coagulation and Flocculation (Chemical Treatment)

Chemical coagulants such as aluminum or iron salts are added and thoroughly mixed with the raw water. After a short period, finely divided, suspended particles coagulate and form gelatinous precipitates. These precipitates are stirred slowly and build up into larger 'flocs' or clumps which finally become heavy enough to settle out.

Sedimentation (Physical Treatment)

Following coagulation and flocculation, the treated water undergoes a quiescent period in a settling basin where the floc is removed through gravity settling. The water is relatively clear after this procedure and the settled material is removed for disposal.

Turbidity and Bacteria Removal by Filtration (Physical Treatment)

After settling, filtration occurs. During this process, the remaining suspended particles are removed by passing the water through a porous filter media such as sand, anthrafilt or a combination of both. These particles are trapped in the media and the filtered water is collected in an underdrain system. The impurities trapped in the filter media are removed by reversing the flow in the filter (backwashing). In some instances, where the turbidity of the raw water is low, direct filtration can occur without the need for sedimentation.

Fluoridation (Chemical Treatment)

Municipalities by by-law may wish to operate a fluoridation system in the water treatment plant. Fluoride used in the drinking water helps prevent dental caries and is considered an acceptable public health measure.

NORTHWESTERN REGION SUMMARY

TREATMENT TYPE	<--- NUMBER --->			<--- ** CAPACITY MIGD ($1000M^3$) --->		
	MINISTRY	MUNICIPAL	TOTAL	MINISTRY	MUNICIPAL	TOTAL
GROUND SOURCE - NO TREATMENT	0	1	1	.000	1.332	1.332 (6.055)
GROUND SOURCE - CHLORINATION ONLY	2	0	2	1.800	.000	1 800 (8.183)
GROUND SOURCE - CHEMICAL TRTMT	1	0	2	1.200	.000	1.200 (5.455)
GROUND SOURCE - PHYSICAL TRTMT	0	1	1	.000	2.304	2.304 (10.474)
GROUND SOURCE - PHY+CHEM TRTMT	0	0	0	.000	.000	.000 (000)
SURFACE SOURCE - CHLORINATION ONLY	3	2	5	.840	13.540	14.380 (65.371)
SURFACE SOURCE - CHEMICAL TRTMT	0	6	6	.000	18.078	18.078 (82.183)
SURFACE SOURCE - PHYSICAL TRTMT	0	1	1	.000	.824	.824 (3.745)
SURFACE SOURCE - PHY+CHEM TRTMT	6	4	10	4.817	19.364	24.181 (109.927)
**** TOTALS ****	12	15	27	8.657 (39.357)	55.442 (252.038)	64.099 (291.394)

CHEMICAL TREATMENT : PROCESSES SUCH AS COAGULATION, FLOCCULATION AND FLUORIDATION WHICH USE CHEMICAL AIDS COME UNDER THIS CATAGORY. ALSO INCLUDED ARE THE CHEMICAL REMOVAL PROCESSES LIKE IRON REMOVAL.

PHYSICAL TREATMENT : PROCESSES USING MECHANICAL AIDS SUCH AS SCREENING, SEDIMENTATION AND FILTRATION COME UNDER THIS CATAGORY.

** MIGD: MILLIONS OF IMPERIAL GALLONS PER DAY
$1000M^3$:THOUSANDS OF CUBIC METRES

CONVERSION FACTOR

1 MGD = 4.546 $1000M^3$

NORTHWESTERN REGION

MUNICIPALITY	TREATMENT TYPE	WATERCOURSE/ SCHEME SOURCE	CAPACITY MIGD (1000M^3)	POPULATION SERVED	OPERATED BY
ATIKOKAN TOWNSHIP ATIKOKAN WTP 220000950	SURFC SOURCE-CHEMICAL TRTMT CHLORINATION FLUORIDATION	ATIKOKAN RIVER	3.100 (14.093)	4744	MUNICIPALITY
BAIRD MADSEN TOWNSHIP MADSEN WTP 210001479	SURFACE SOURCE-CHLORINATION	RUSSETT LAKE	.140 (.636)	300	MINISTRY
